- ✿ Introduction:
  - ✿ current situation and challenges in p2p networks
- ✿ Context of the work
  - ✿ MOSAICA
    - ✿ goals, system architecture, functionality
- ✿ The proposed approach
  - ✿ concept
  - ✿ tools used, modular functionality, layered architecture
- ✿ P2P Content Management System
  - ✿ use cases, uploading and searching content, deployed testbed
- ✿ Conclusions

# Introduction

---

- ☼ Current situation and challenges in p2p networks

# Current situation in p2p

---

- unstructured architectures
  - the network is flooded with query messages to locate streams and files (all nodes receive the query)
- **structured** architectures
  - based on Distributed Hash Tables (**DHT**) that maintain an index to the available resources, facilitating location
  - query messages are forwarded to only some nodes, which are more likely to have the location of the desired resource

# Challenges in p2p for multimedia

- generally, users when searching for multimedia resources
  - do **not know the exact name** of the file they are looking for
  - often want to receive a **useful set of results** that are clearly **related** to the subject they are interested in
- while unstructured designs allow this kind of proximity behavior
  - at the cost of larger search times and increased network traffic
- common structured, DHT-based, designs do not
  - search is performed using a hash key and only exact matches are returned

# Challenges in p2p - semantic queries

- Current research initiatives include
  - Locality Sensitive Hashing (LSH) techniques (nearest-neighbor search problem in a Euclidean space)
  - hierarchical multiple indexes, allowing query-to-query mapping and thus the implementation of a recursively query process
  - the CUBIT project at Cornell University using an overlay where peers are organized in concentric rings
- though promising good results, require complex management and/or processing of intermediate results

# Context of the work

---

- ✻ MOSAICA

- ✻ goals, system architecture, functionality

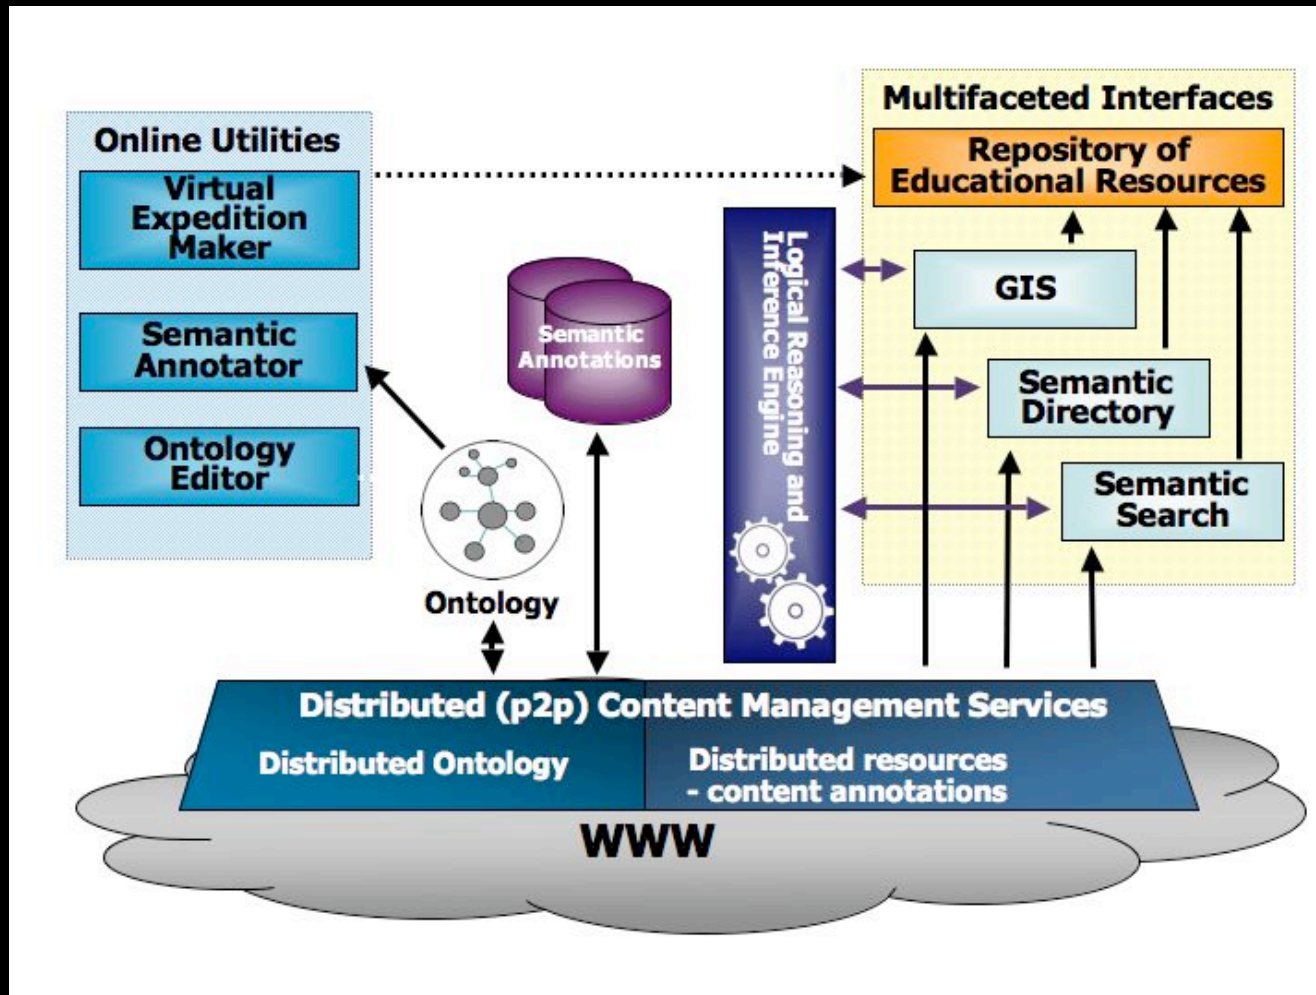

# MOSAICA goals

---

- Leveraging Web2.0-based technologies to enhance critical thinking and open-mindedness
- tool-box of Web based technologies for the preservation and sharing of cultural heritage resources (photos, documents, video, sound, etc.)
  - sharing of cultural resources owned by private people or organizations such as museums.
  - motivate users to create innovative experiences, **multimedia virtual expeditions**, telling their personal stories, and sharing them with remote peers, via a rich interactive environment
- reach as many people as possible
  - **low cost**, **high availability**, simplicity

# MOSAICA architecture

# MOSAICA functionality

---

- **Explorative** usage
  - visit places of interest by zooming in on an area on MOSAICA's geographical interface, obtaining related multimedia info,
  - or by exploring MOSAICA semantic directory, or by submitting a query.
- **Collaborative** usage
  - annotate digital cultural objects with free-text comments or with semantic inter-related concepts using the MOSAICA Ontology
  - submit and exposed to the public annotated resources
  - design own Virtual Expeditions, using digital resources available in MOSAICA, and suggest them to other visitors by storing them in the MOSAICA P2P repository
- **Guided** usage
  - select ready-made, thematically-oriented Virtual Expeditions, from within the MOSAICA distributed repository

# MOSAICA functionality

- Explorative usage

The screenshot displays the MOSAICA web application interface. At the top, there is a navigation bar with the MOSAICA logo and links for "Who are we?" and "What is MOSAICA?". Below this is a menu with options: "Investigate", "Explore", "Resources", "Virtual Expeditions", and "Preferences".

The main content area is divided into two sections. On the left is a "Metadata" panel with the following information:

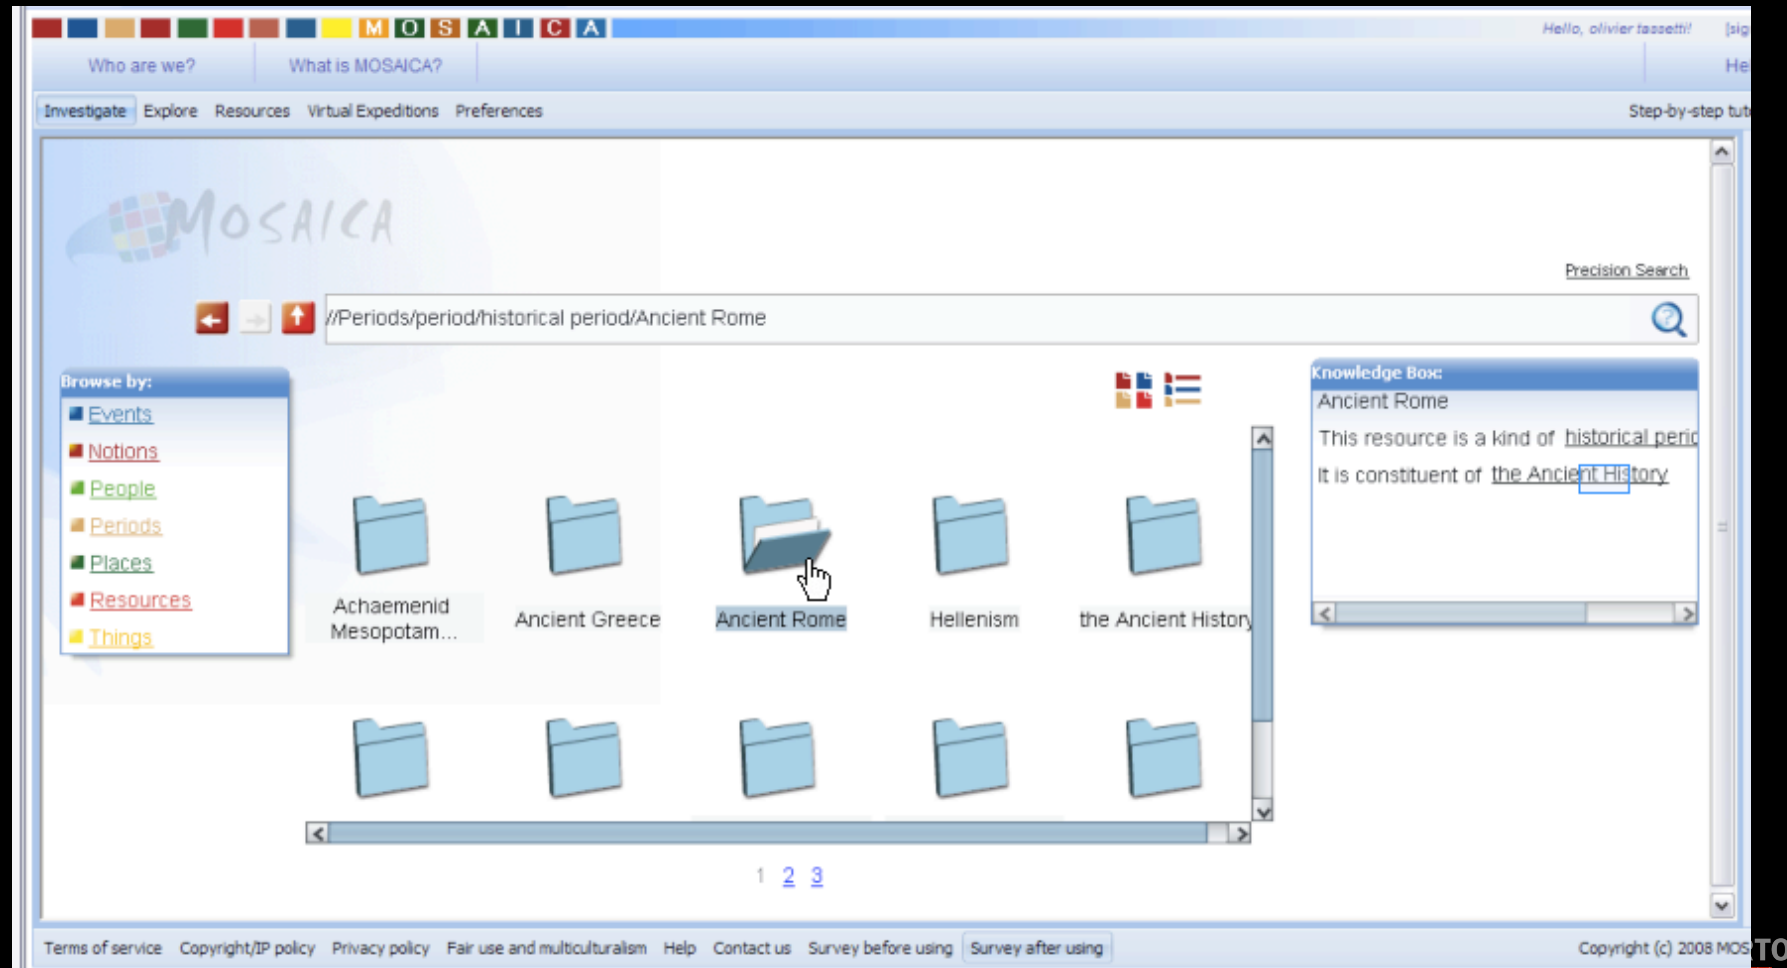

Metadata	Knowledge box
Title	The Middle East through
Contributed by:	Korda
Contributed on:	2008.08.18 11:06
depicts:	Ancient Middle East

Below the metadata panel is a dark blue square with navigation arrows. The right section features a map of the Ancient Middle East, color-coded by region. Labeled regions include Egypt, HAM, Dedan, OPHIR, SHEBA, SHEBA, JOKTAN, SHEMA, ASSYRIA, ASSHUR, ELAM, and PHILISTINES. A dashed box highlights a specific area in the north, and a mouse cursor is pointing at the HAM region. A small inset map at the bottom left shows the location of the main map area within a larger geographical context.

At the bottom of the interface, there is a footer with links for "Terms of service", "Copyright/IP policy", "Privacy policy", "Fair use and multiculturalism", "Help", "Contact us", "Survey before using", and "Survey after using".

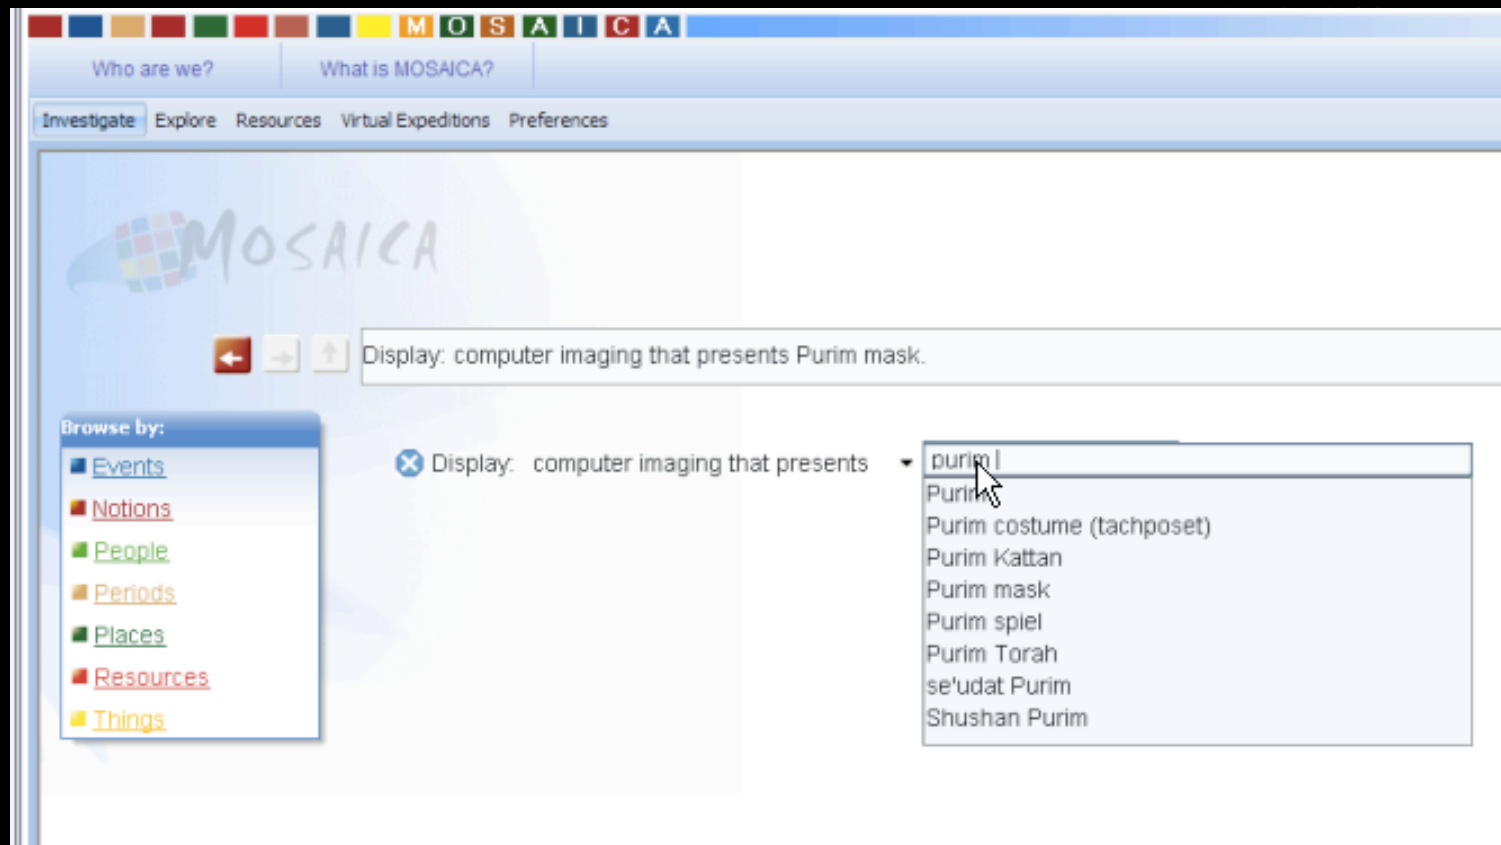

# MOSAICA functionality

# MOSAICA functionality

# MOSAICA functionality

# The proposed approach for the distribution and management of resources

---

- ☼ concept, tools used
- ☼ modular functionality, layered architecture

# Concept

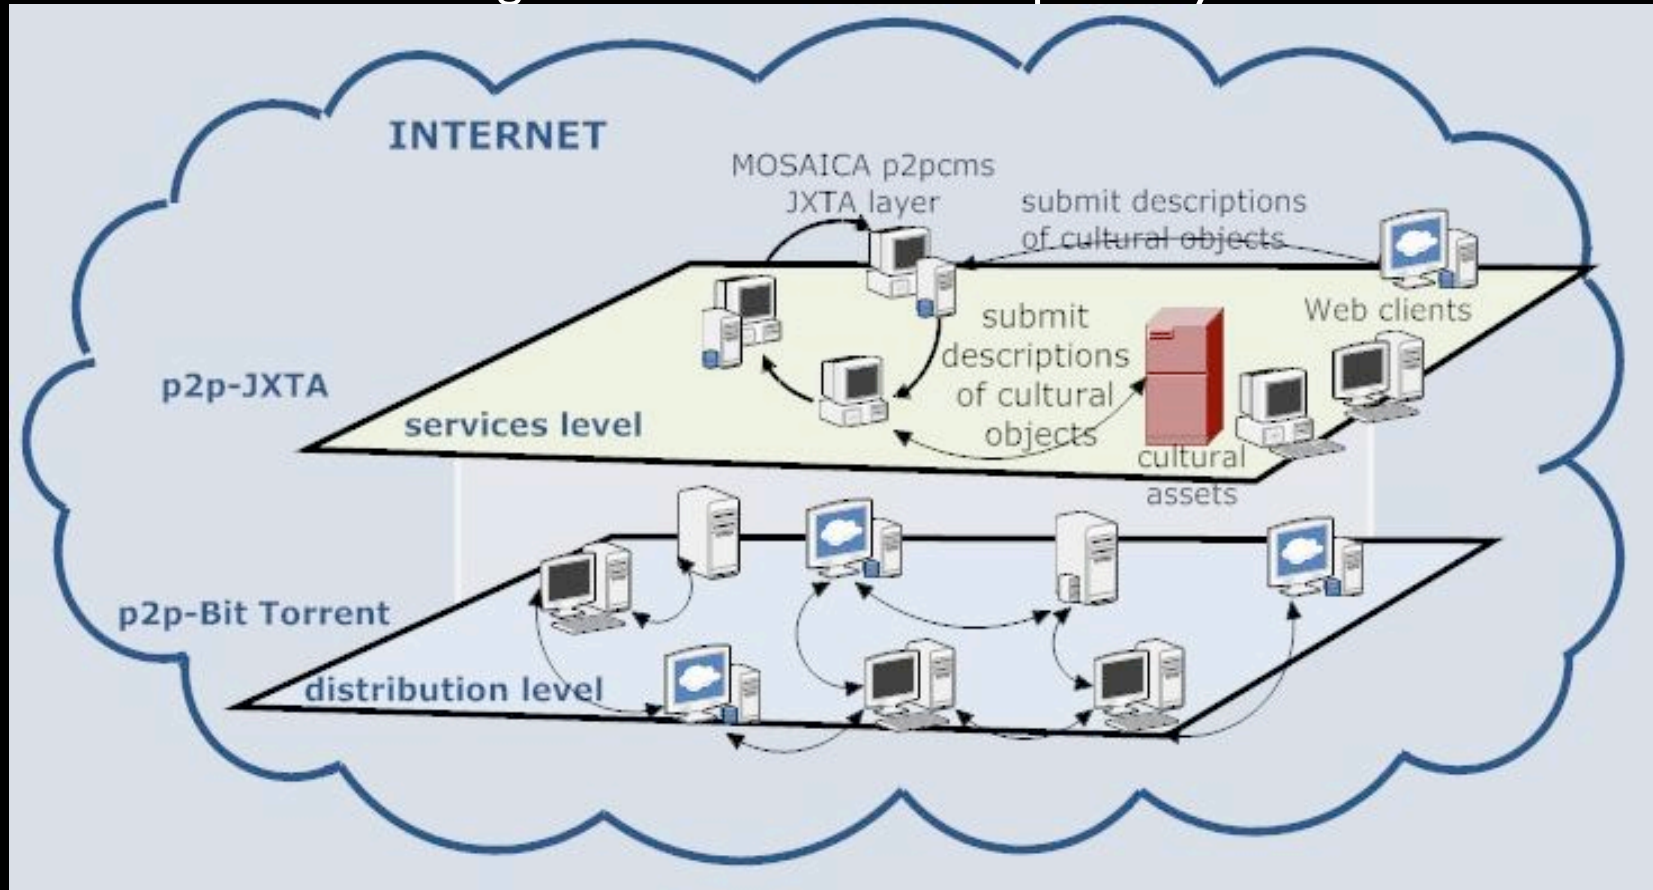

---

- The challenge for the MOSAICA repository and content management system
  - to allow efficient semantic search
  - low-cost, usability, high-availability, simplicity
- The solution
  - p2p design adopting a **two layer approach**
    - upper layer handling semantic and keyword based queries
      - exposing distributed services through a **Web Services** interface
        - notably the **Ontology** service
      - built using the **JXTA** framework and **distributed databases**
    - lower layer handling **media resources distribution and download**
      - based on **DHT** p2p architecture, notably using **Bit Torrent** protocols

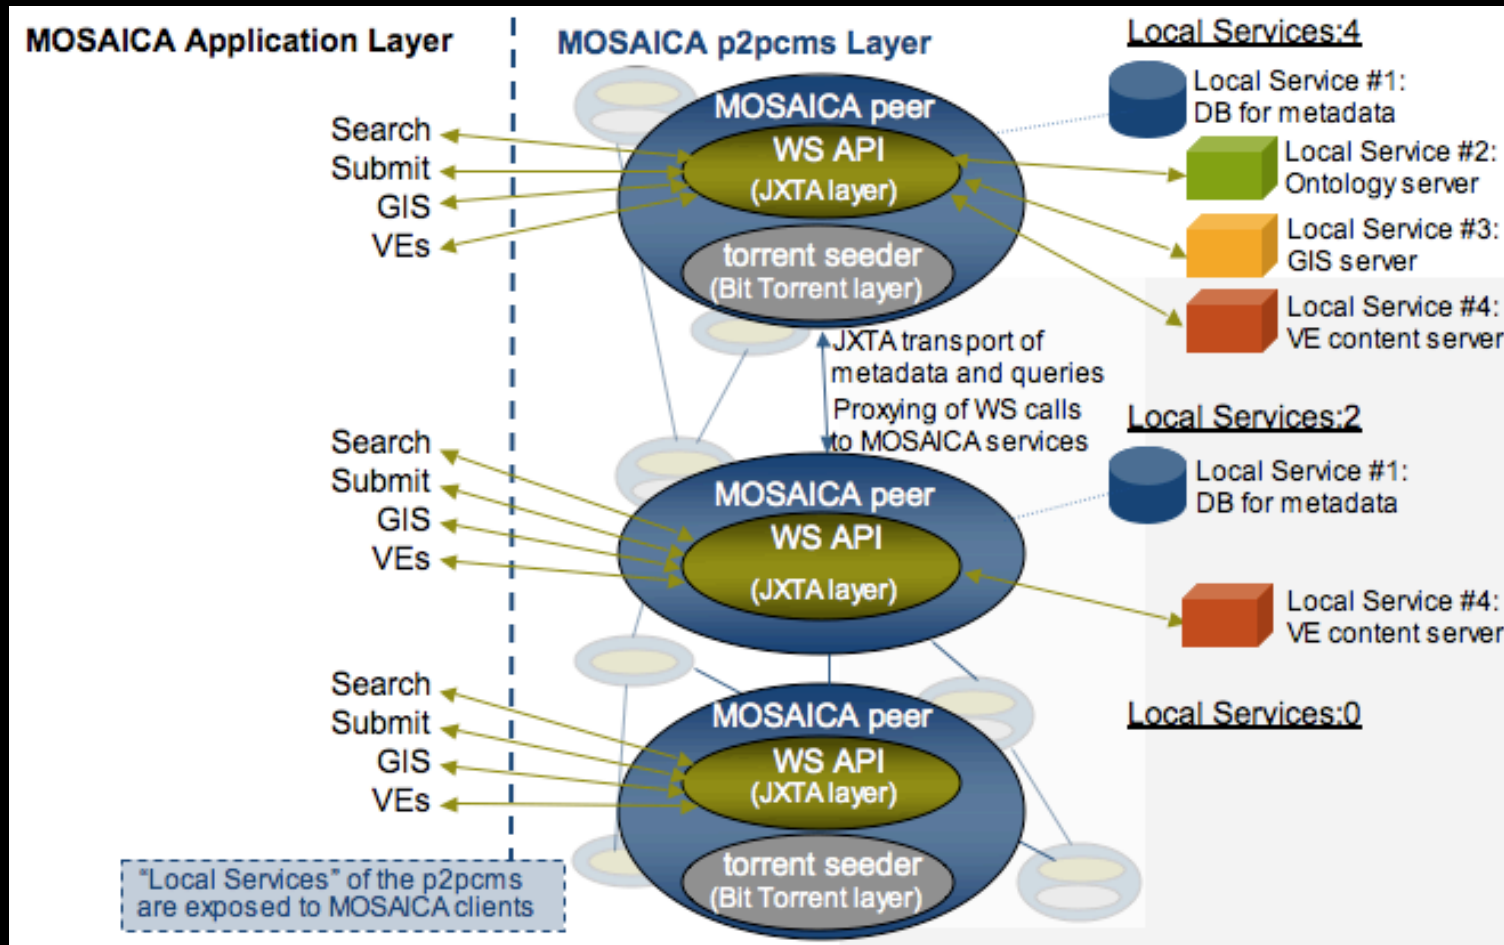

# Concept

- The challenge for the MOSAICA repository and content

- based on **DHT** p2p architecture, notably using **Bit Torrent** protocols

# p2p-cms modular functionality

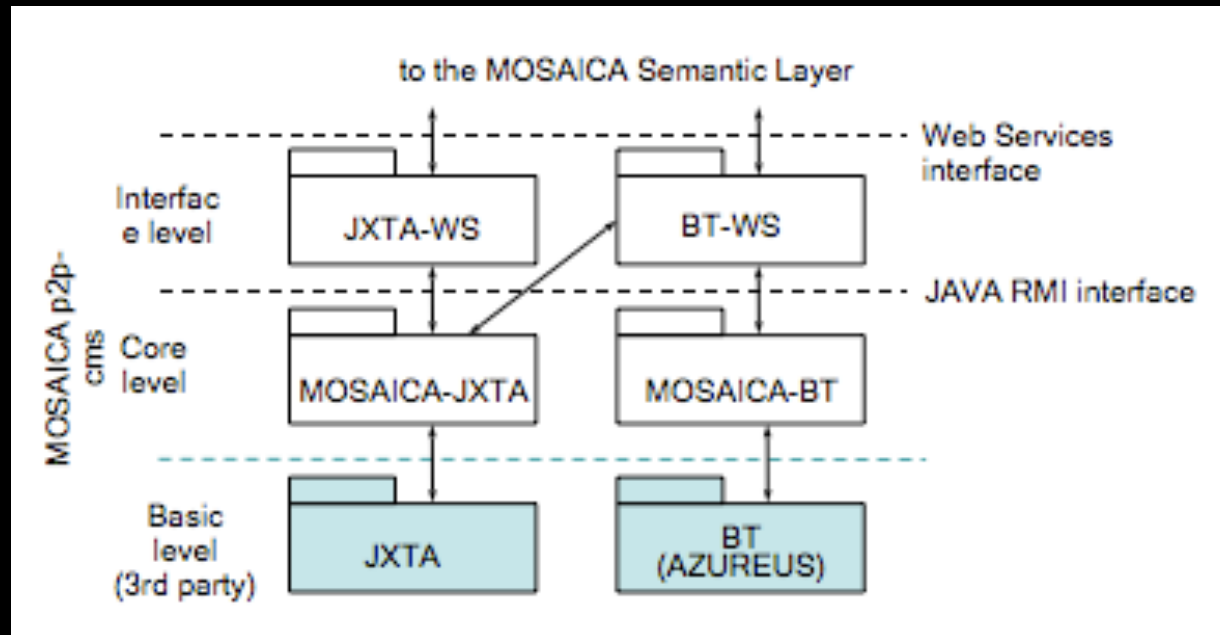

# p2p-cms functionality

Method	Description
<code>login(LUser, password)</code>	Login method. It returns a session hash if user credentials are correct.
<code>registerContent(LSession, contentDat)</code>	Content data XML is sent. <code>ContentID</code> is returned
<code>requestContent(LSession, contentID, boolean wait)</code>	XML describing content (title, torrent binary, etc.) is returned
<code>searchContent(LSession, XMLquery, boolean wait)</code>	Query contents using a XML query. XML list of found contents, for this user groups, is returned
<code>removeContent(LSession, content ID)</code>	Remove index to content
<code>addMetadata(Lsession, content ID, indextype, property, value)</code>	Submits new semantic descriptions to be propagated to the distributed databases
<code>removeMetadata (Lsession, content ID, indextype, property, value)</code>	Eliminates a metadata record
<code>changePassword (Lsession, user, oldpassword, newpassword)</code>	Updates password for user

# p2p-cms architecture

- modular and layered architecture

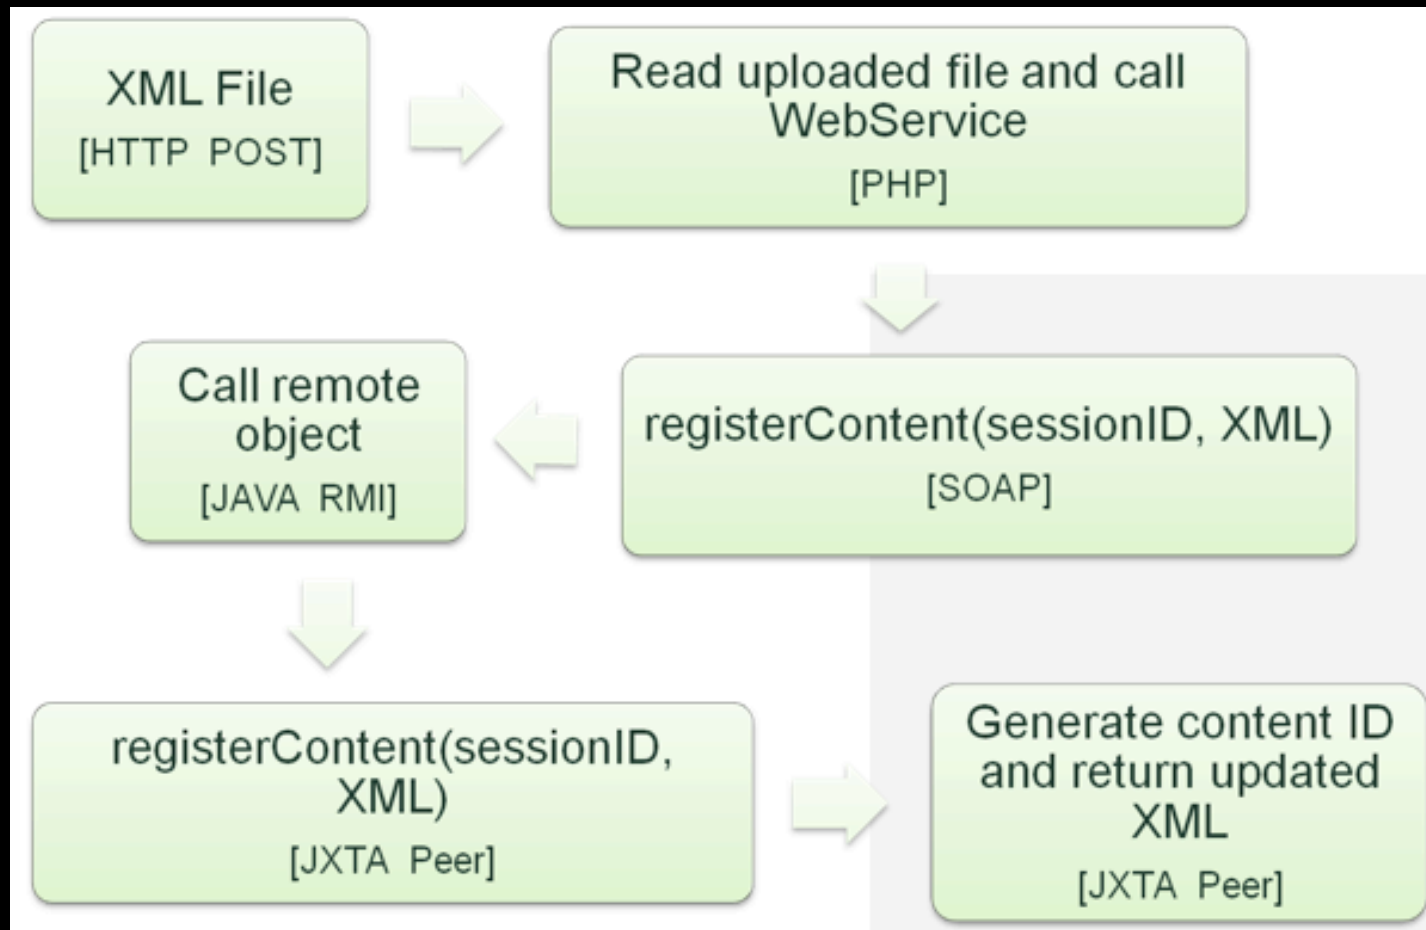

# P2P Content Management System

---

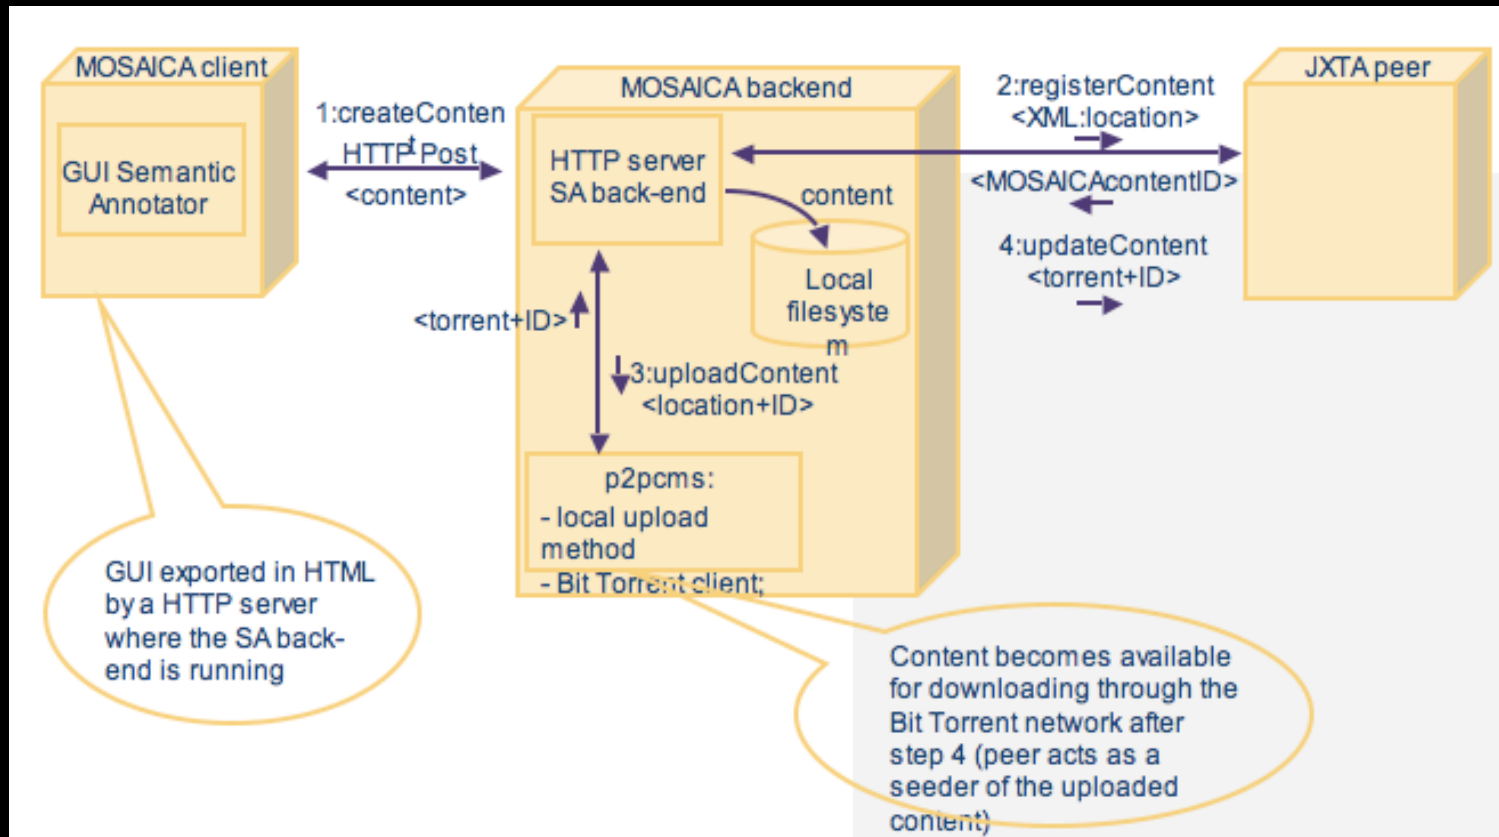

- ☼ use cases supported
  - ☼ uploading and searching content
- ☼ testbed deployed

# Some important use cases

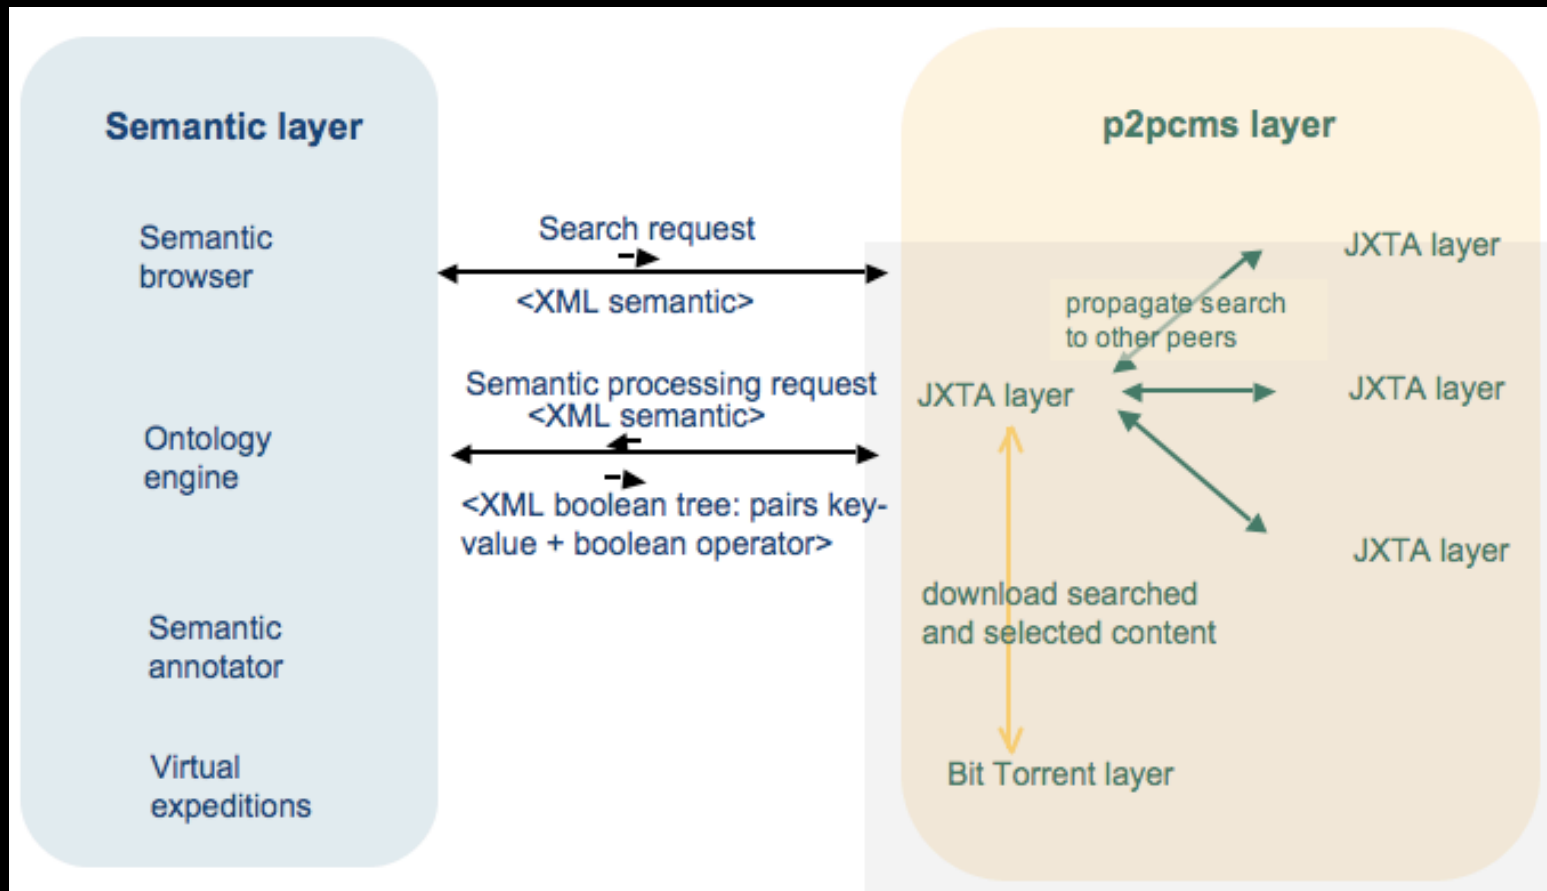

# Some important use cases

# Some important use cases

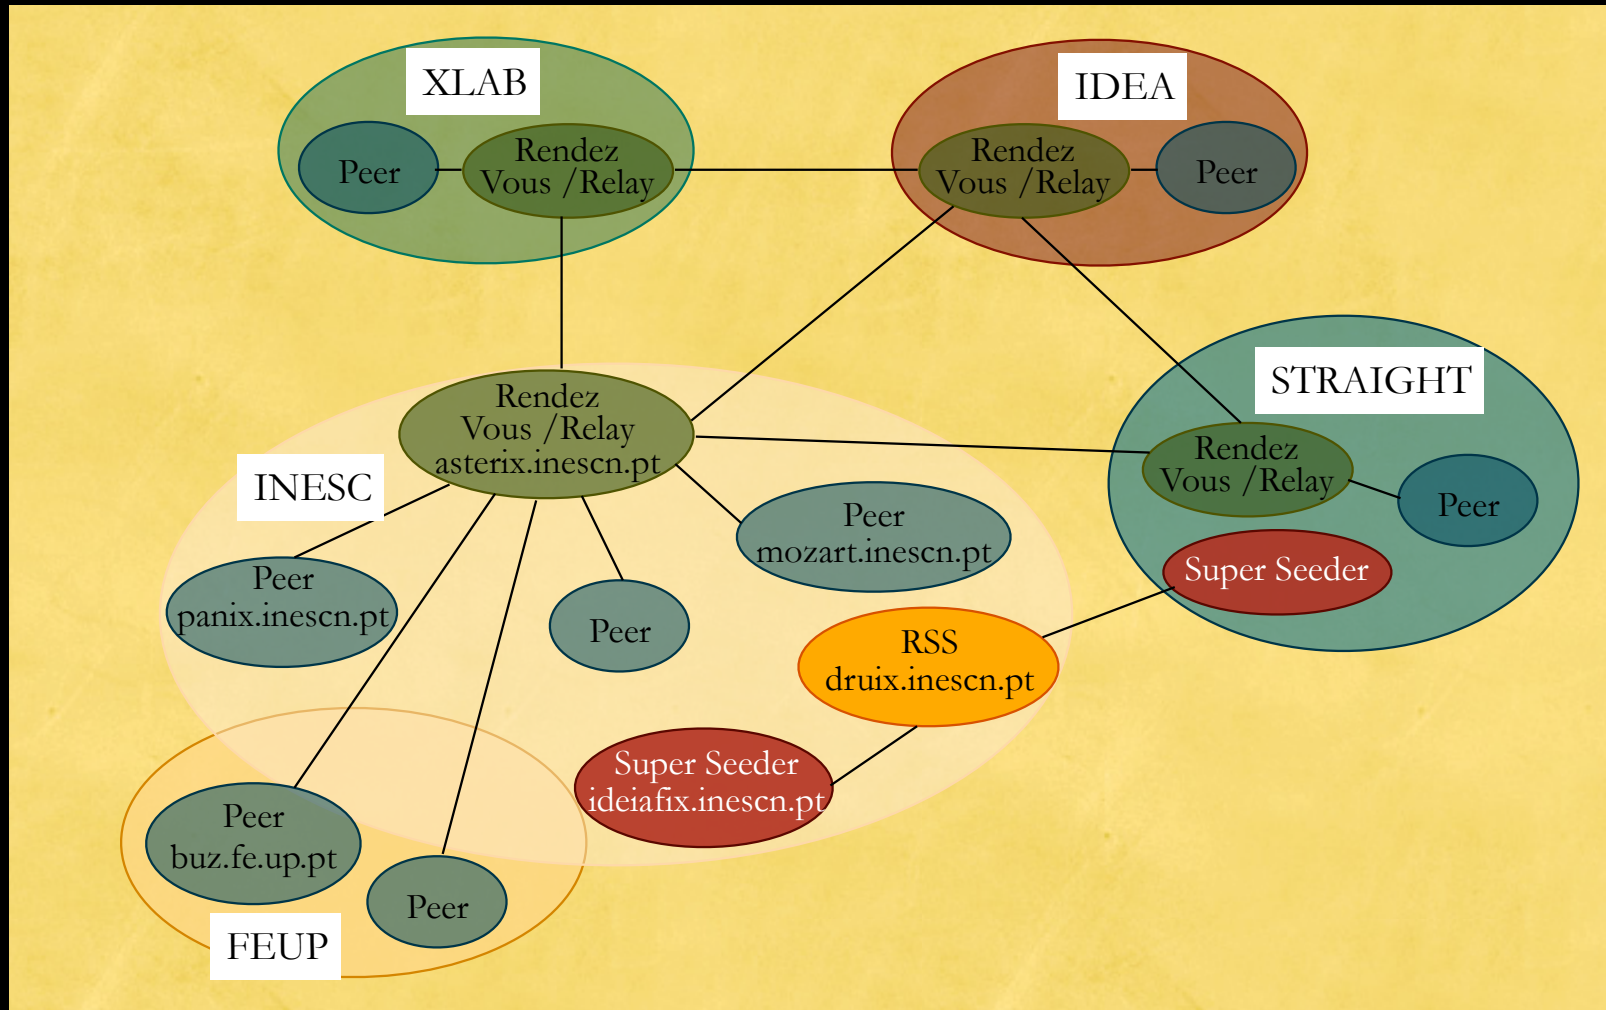

# testbed deployed

---

- Needed for operational testing, integration and data gathering for simulation and evaluation
- Includes JXTA and Bittorrent overlays
- A Rendezvous/Relay peer, normal peer, super seeder and RSS server can be installed in only one machine (independent applications)
- Needed software : P2P-cms application, Azureus, JXTA Shell, Web server (for RSS feeds), Mysql and AXIS 2 (with RSS and peer webservice)

# testbed deployed

# Conclusions

---

- ✱ The two-layered approach
  - ✱ by which metadata is manipulated in one layer and content in the other layer
- ✱ enables to obtain an optimal solution
  - ✱ on one side, it enables to take advantage of the great efficiency of DHT (Distributed Hash Tables) for the distribution of and access to media resources;
  - ✱ on the other hand, through the implementation of distributed databases for managing metadata, it enables to overcome the limitation of DHT-based P2P networks for performing semantic-based searches
  - ✱ additionally it enables the use of simple search mechanisms
- ✱ however, semantic search is only possible through the use of an ontology server
  - ✱ XML based semantic queries are decomposed in a series of boolean expressions which are then used for indexing and searching
- ✱ Still, performance and scalability tests need to be performed

Thank you very much for your attention!
