ABSTRACT

This paper summarizes the possible approaches suitable for the modelling of cable and fibre dynamics in the framework of various mechanical systems. Force representation of a cable, a point-mass model, an absolute nodal coordinate formulation and a general model based on Hamilton’s principle are introduced. The QuadroSphere tilting mechanism with a spherical motion of a platform and an accurate measurement of its position is introduced.

Keywords: cable, multibody dynamics, nonlinear force, vibration

INTRODUCTION

Cables and fibres can play an important role in the design of many machines. One of the most interesting applications is the replacing of chosen rigid elements of a manipulator or a mechanism with cables. The main advantage of this design is achievement of a lower moving inertia, which leads to a higher mechanism speed, a large range of motion and the possibility of antibacklash property. The drawbacks can be related to the fact that cables should be only in tension in the course of a motion. This paper summarizes the possible approaches suitable to the modelling of cable dynamics in the framework of various mechanical systems.

Fig. 1 - The QuadroSphere tilting mechanism

The motivation is the development of a cable model, which could be efficient for the usage in a mechatronic model of a manipulator consisting of cables and an end-effector whose motion is driven by cables - particularly for the usage in the model of QuadroSphere (see Fig. 1 and...
The QuadroSphere is a tilting mechanism with a spherical motion of a platform and an accurate measurement of its position. The platform position is controlled by four fibres; each fibre is guided by a pulley from linear guidance to the platform. The numerical model of QuadroSphere will serve for the investigation of different possible strategies of the control of this active structure superimposed to the end-effector of the cable-driven mechanism in order to improve the end-effector positioning accuracy and the operational speed.

Flexible multibody dynamics is a rapidly growing branch of computational mechanics and many industrial applications can be solved using newly proposed flexible multibody dynamics approaches. The studied problems are characterized by a general large motion of interconnected rigid and flexible bodies with the possible presence of various nonlinear forces and torques. There are many approaches to the modelling of flexible bodies in the framework of multibody systems (Hajžman, 2008). Comprehensive reviews of these approaches can be found in Shabana (1997) or in Wasfy (2003). Further development together with other multibody dynamics trends was introduced in Schiehlen (2007). Details of multibody formalisms and means of the creation of equations of motion can be found e.g. in Stejskal (1996), Awrejcewicz (2012).

The simplest way how to incorporate cables in the equations of motion of a mechanism is the force representation of a cable (e.g. Diao, 2009; Polach, 2015b). It is supposed that the mass
of cables is small to such an extent comparing to the other moving parts that the inertia of cables is negligible with respect to the other parts. The cable is represented by the force dependent on the cable deformation and its stiffness and damping properties. A variable length of the cable due to wiring can be easily described using the force approach. This way of the cable modelling is probably the most frequently used in the cable-driven robot dynamics and control (e.g. Heyden, 2006; Zi, 2008).

A more accurate approach is based on the representation of the cable using a point-mass model (e.g. Kamman, 2001; Polach, 2014; Ottaviano, 2015). It has the advantage of a lumped point-mass model. The point masses can be connected by forces or constraints. Wiring of a cable can be also simulated and a detailed model of a wiring mechanism can be observed. In the case of the manipulator mechatronic model consisting of cables and an end-effector whose motion is driven by cables (e.g. in the case of the QuadroSphere model - Polach, 2015a) utilization of the point-mass model of a cable proved to be very prospective.

In order to represent bending behaviour of cables their discretization using the finite segment method (Shabana, 1997) or so called rigid finite elements (Wittbrodt, 2006) is possible. Other more complex approaches can utilize nonlinear three-dimensional finite elements (Freire, 2006).

A very promising approach usable for the cable modelling is a so called absolute nodal coordinate formulation (ANCF), which is based on the discretization of a cable or a fibre to nonlinear finite elements (Shabana, 1997; Gerstmayr, 2012; Liu, 2012; Hajţman, 2015; Bulín, 2015; Bulín, 2017). Absolute nodal positions and slopes are considered to be nodal coordinates of the ANCF elements. The formulation leads to a constant mass matrix and highly nonlinear stiffness matrix. The model can be efficiently used for the investigation of various contact problems related to cables or fibres.

Another approach used for creation of a general model involving cables with distributed mass and time-varying length is based on Hamilton’s principle, which serves to achieve a system of partial differential equations describing the cable dynamics (Du, 2015). To solve the system of dynamic equations, the Ritz-mode method with polynomial shape functions is employed and the system of partial differential equations is converted into ordinary differential equations. The accuracy of the cable model depends on the order of the used polynomial mode functions. This approach is suitable for the modelling of cable-driven manipulators with distributed mass flexible cables.

**FORCE AND POINT-MASS REPRESENTATION OF THE CABLE**

Model of the mechanical system with the end-effector attached to the frame using two cables is given as an example for introducing the force (see Fig. 3) and the point-mass (see Fig. 4) representation of the cable. The free length of the left cable is \( l_1 \), the free length of the right cable is \( l_2 \) and abbreviation EF denotes the end-effector (the weight) in Fig. 3 and Fig. 4.

The equation of motion of the system from Fig. 3 (force representation of the cable) can be written as a differential equation of the second order

\[
 m \ddot{\mathbf{r}} + b_1 \frac{d\mathbf{l}_1}{dt} + b_2 \frac{d\mathbf{l}_2}{dt} + k_1 \mathbf{dl}_1 + k_2 \mathbf{dl}_2 = \mathbf{f},
\]

where \( \mathbf{r} \) is the position vector of the end-effector, \( \ddot{\mathbf{r}} \) is the vector of acceleration of the end-effector, \( \mathbf{r}_A \) is the position vector of attachment of the left cable to the frame, \( \mathbf{r}_b \) is the position vector of attachment of the right cable to the frame, \( \mathbf{r}_{AEF} = \mathbf{r} - \mathbf{r}_A \) is the vector from...
point A (i.e. the attachment of the left cable to the frame) to the end-effector, $\mathbf{r}_{BEF} = \mathbf{r} - \mathbf{r}_B$ is the vector from point B (i.e. the attachment of the right cable to the frame) to the end-effector, 

$$d_1 = -\left(\mathbf{r}_{AEF} - l_1\right) \frac{\mathbf{r}_{AEF}}{|\mathbf{r}_{AEF}|} H\left(|\mathbf{r}_{AEF}| - l_1\right)$$

is the vector of deformation of the left cable, 

$$|\mathbf{r}_{AEF}| = \sqrt{\mathbf{r}_{AEF}^T \mathbf{r}_{AEF}} , \quad d_2 = -\left(\mathbf{r}_{BEF} - l_1\right) \frac{\mathbf{r}_{BEF}}{|\mathbf{r}_{BEF}|} H\left(|\mathbf{r}_{BEF}| - l_2\right)$$

is the vector of deformation of the right cable, 

$$|\mathbf{r}_{BEF}| = \sqrt{\mathbf{r}_{BEF}^T \mathbf{r}_{BEF}} , \quad H\left(\right)$$

is the Heaviside’s step function, $\mathbf{f}$ is the vector of force acting on the end-effector, $t$ is time, $m$ is the mass of the end-effector, $k_1$ is the stiffness of the left cable, $k_2$ is the stiffness of the right cable, $b_1$ is the damping coefficient of the left cable and $b_2$ is the damping coefficient of the right cable.

Fig. 3 - Model of the mechanical system with the end-effector attached to the frame using two cables with the force representation of the cable (in absolute coordinate system)

For each node of the system from Fig. 4 (point-mass representation of the cable) the following equation of motion can be written

$$m_i \ddot{\mathbf{r}}_i + b_i \frac{d\mathbf{r}_i}{dt} + b_{i+1} \frac{d\mathbf{r}_{i+1}}{dt} + k_i d_1 + k_{i+1} d_{i+1} = \mathbf{f}_i ,$$

(2)

where $\mathbf{r}_i$ is the position vector of node $i$ (or end-effector), $\ddot{\mathbf{r}}_i$ is the vector of acceleration vector of node $i$, $\mathbf{r}_{i+1}$ is the position vector of node $i-1$, $\mathbf{r}_{i+1}$ is the position vector of node $i+1$, $\mathbf{r}_{i+1} = \mathbf{r}_i - \mathbf{r}_{i+1}$ is the vector from node $i-1$ to node $i$, $\mathbf{r}_{i, i+1} = \mathbf{r}_i - \mathbf{r}_{i+1}$ is the vector from node $i+1$ to node $i$, $l_i$ is the free length of the part of the cable between node $i-1$ and node $i$, $l_{i+1}$ is the free length of the part of the cable between node $i$ and node $i+1$, 

$$d_1 = -\left(\mathbf{r}_{i, i+1} - l_1\right) \frac{\mathbf{r}_{i, i+1}}{|\mathbf{r}_{i, i+1}|} H\left(|\mathbf{r}_{i, i+1}| - l_1\right)$$

is the vector of deformation of the part of the cable between node $i-1$ and node $i$, $|\mathbf{r}_{i, i+1}| = \sqrt{\mathbf{r}_{i, i+1}^T \mathbf{r}_{i, i+1}} , \quad d_{i+1} = -\left(\mathbf{r}_{i, i+1} - l_{i+1}\right) \frac{\mathbf{r}_{i, i+1}}{|\mathbf{r}_{i, i+1}|} H\left(|\mathbf{r}_{i, i+1}| - l_{i+1}\right)$$

is the vector of deformation of the part of the cable between node $i$ and node $i+1$,
\[ |f_i| = \sqrt{|r_{i,i+1}^T r_{i,i+1}|}, \quad f_i \text{ is the vector of force acting on node } i, \quad m_i \text{ is the mass of node } i, \quad k_i \text{ is the stiffness of the part of the cable between node } i-1 \text{ and node } i, \quad k_{i+1} \text{ is the stiffness of the part of the cable between the node } i \text{ and node } i+1, \quad b_i \text{ is the damping coefficient of the part of the cable between node } i-1 \text{ and node } i, \quad b_{i+1} \text{ is damping coefficient of the part of the cable between node } i \text{ and node } i+1. \]

Resultant equations of motion of all nodes and the end-effector lead to the system of differential equations of the second order in a matrix form.

**ANCFC CABLE MODEL**

A planar ANCF beam element of length \( l \) with two nodes (see Fig. 5) is briefly introduced. Global position \( \mathbf{r} = [r_x, r_y]^T \) of an arbitrary beam point determined by parameter \( p \) can be written as

\[\mathbf{r}(p) = \mathbf{S}(p) \mathbf{e}, \quad \mathbf{e} = [e_1, e_2, ..., e_s]^T, \]

where \( \mathbf{S} \in \mathbb{R}^{2,s} \) is the global shape function matrix, \( \mathbf{e} \) is the vector of element nodal coordinates and \( p \in (0, l) \) is the parameter of a curve.
Particular nodal coordinates in the case of cubic shape functions (Shabana, 2005) are

\[ e_1 = r_x(0), \quad e_2 = r_y(0), \quad e_3 = r_z(0) = \frac{\partial r_x(0)}{\partial \xi}, \quad e_4 = r_y(0) = \frac{\partial r_z(0)}{\partial \eta}, \]

\[ e_5 = r_x(l), \quad e_6 = r_y(l), \quad e_7 = r_z(l) = \frac{\partial r_x(l)}{\partial \xi}, \quad e_8 = r_y(l) = \frac{\partial r_z(l)}{\partial \eta}. \]  

(4)

The global shape function matrix in the case of the planar beam element is defined as

\[ S = [s_1 I \quad s_2 I \quad s_3 I \quad s_4 I], \quad I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \]

\[ s_1 = 1 - 3\zeta^2 + 2\zeta^3, \quad s_2 = l(\zeta - 2\zeta^2 + \zeta^3), \quad s_3 = 3\zeta^2 - 2\zeta^3, \quad s_4 = l(\zeta^3 - \zeta^2), \quad \zeta = \frac{P}{l}. \]  

(5)

Standard procedures (e.g. the Lagrange equations or the principle of virtual work) can be used in order to derive a mathematical model of the planar ANCF beam element. Kinetic energy of the element of material density \( \rho \) is

\[ E_k = \frac{1}{2} \int_0^l \rho A \dot{r}^T \dot{r} \, dp = \frac{1}{2} \dot{\varepsilon}^T \int_0^l \rho A S^T S \, dp \, \dot{\varepsilon} = \frac{1}{2} \dot{\varepsilon}^T M_e \dot{\varepsilon}, \]

where \( M_e \) is the constant element mass matrix in the case of this formulation.

Strain energy \( E_p \) of the element is used for the derivation of elastic forces in the ANCF model and the form of an adopted elasticity model determines the complexity of the whole model. In Shabana (2005), there are several approaches, which employ the separation of strain energy of longitudinal deformation \( E_{pl} \) and strain energy of transverse (bending) deformation \( E_{pt} \) as

\[ E_p = E_{pl} + E_{pt} = \frac{1}{2} \int_0^l E A \varepsilon_i^2 \, dp + \frac{1}{2} \int_0^l E I \kappa^2 \, dp, \]

where \( E \) is the Young modulus, \( A \) is the area of the cross-section and \( I \) is the second moment of the area about a transverse axis. The possible models are then classified according to the expressions for longitudinal strain \( \varepsilon_i \) and curvature \( \kappa \). General expressions for these quantities are

\[ \varepsilon_i = \frac{1}{2} \left( \dot{r}^T \dot{r} - 1 \right), \quad \kappa = \frac{d^2r}{ds^2}, \]

(8)

where \( ds \) is the infinitesimal arc length of the beam, which can be expressed as

\[ ds = \sqrt{\dot{r}^T \dot{r}} \, dp. \]

(9)

In general case, the vector of the element elastic forces \( Q_e \) can be written as

\[ Q_e = \left( \frac{\partial E_p}{\partial \varepsilon} \right) = \int_0^l E A \varepsilon_i \frac{\partial \varepsilon_i}{\partial \varepsilon} \, dp + \int_0^l E I \kappa \frac{\partial \kappa}{\partial \varepsilon} \, dp = Q_{el} + Q_{et} = [K_i(\varepsilon) + K_t(\varepsilon)] \varepsilon, \]

(10)
where $Q_{el}$ is element longitudinal elastic force, $Q_{ek}$ is element transverse elastic force, $K_{l}(e)$ is (nonlinear) longitudinal stiffness matrix and $K_{t}(e)$ is (nonlinear) transverse stiffness matrix.

The way of the strain and curvature calculation can be simplified by several presuppositions of the way of the beam deformation. In Berzeri (2000) several suitable models for both longitudinal and transverse elastic forces are introduced.

The whole model of the ANCF element is of the form

$$M_{e} \ddot{e} + K_{e}(e)e = Q_{ek},$$

(11)

and is characterized by constant mass matrix $M_{e}$, strongly nonlinear stiffness matrix $K_{e}(e)=K_{l}(e)+K_{t}(e)$ derived using the strain energy and by vector of external forces $Q_{ek}$.

The assembling of a discretized flexible body model is straightforward and can be extended by a suitable model of viscous forces

$$M \dot{q} + B(\dot{q}, q) \dot{q} + K(q)\dot{q} = Q_{k},$$

(12)

where $q$ is the vector of all elastic coordinates of the flexible body and $B$ is damping matrix. This model can be combined with models of other flexible or rigid bodies and with the model of kinematic joints.

**ANALYTICAL APPROACH TO THE MODELLING OF THE CABLE MECHANISM DYNAMICS BASED ON HAMILTON’S PRINCIPLE**

The basis of analytical approach to the modelling of the cable mechanism dynamics based on Hamilton’s principle is given in Du (2015).

Part of the cable mechanics is depicted in Fig. 6.

Kinetic $T_{i}$ and potential $V_{i}$ energies of the pulley and the cable wound on it can be expressed in form (without subscript of $i$-th cable)

$$T_{i} = \int_{0}^{\frac{\xi}{d}} \frac{1}{2} \mu \dot{r}^T r \, ds + \frac{1}{2} I_{d} \dot{\xi}^2 = \frac{1}{2} (\mu \xi + \kappa) \dot{\xi}^2, \quad s \in (0, \xi), \quad I_{d} = \kappa d^2,$$

$$V_{i} = \int_{0}^{\xi/d} \mu g d (r_{d}^T e_{3} + d \sin \varphi) d\varphi = -\mu g d \xi r_{d}^T e_{3} + \mu g d^2 \left(1 - \cos \frac{\xi}{d} \right),$$

(13)

where $\mu$ is mass per unit length of the cable, $e_{3}$ is the unit vector in the direction of gravity, $d$ is the radius of the pulley, $g$ is the gravitational acceleration and position vectors $r$ and $r_{d}$ are evident from Fig. 6.

Kinetic $T_{2}$ and potential $V_{2}$ energies (gravitational and deformational) of the deployed cable can be expressed in form

$$T_{2} = \int_{\xi}^{L} \frac{1}{2} \mu \dot{r}^T r \, ds,$$

$$V_{2} = \int_{\xi}^{L} \left( \frac{1}{2} EA \varepsilon^2 - \mu g d r_{d}^T e_{3} \right) ds, \quad \varepsilon = |r| - 1, \quad |r| = \sqrt{r^{T} r}, \quad r = \frac{\partial r}{\partial s},$$

(14)
where $E$ is the Young modulus of the cable material and $A$ is the cable cross section area.

If the end-effector is e.g. point mass, kinetic and potential energies of the end-effector take form

$$\begin{align*}
T_3 &= \frac{1}{2} m \dot{r}_l^T \dot{r}_l , \\
V_3 &= -m g r_i^T e_3 ,
\end{align*}$$

where $r_i$ is the position vector of the end-effector (identical with end point of each cable) and $m$ is mass of the end-effector. In other cases the end points of cables will be coupled with coordinates of end-effector by means of kinematical boundary conditions.

For assemblage of equations of motion can be used Hamilton’s principle in form

$$\delta \int_0^T \left[ \sum_{i=1}^N \left( T_{li} - V_{li} + T_{2i} - V_{2i} \right) + T_3 - V_3 \right] dt = 0 ,$$

where $t$ is time and subscripts $i$ correspond to individual cables and pulleys. Having performed the variation of Hamilton’s functional it can be accessed to relation

$$\begin{align*}
&\left( \frac{1}{2} \mu \ddot{r}_i + \left( \mu \ddot{r}_i + \kappa \right) \dot{r}_i \right) \delta \ddot{r}_i + m \dot{r}_i^T \dot{r}_i \\
&- \mu \dot{r}_i^T \delta \dot{r}_i \delta \ddot{r}_i dt - \int \sum_{i=1}^N \left( \mu \dot{r}_i^T \delta \dot{r}_i \right) \delta \ddot{r}_i dt + \sum_{i=1}^N \delta m \dot{r}_i^T \delta e_3 dt + \sum_{i=1}^N \delta \mu g \dot{r}_i^T \delta e_3 dt + \\
&\sum_{i=1}^N \delta \left( \frac{1}{2} E A r_i^T - r_i^T \right) r_i \delta \ddot{r}_i + \sum_{i=1}^N \delta \left( \mu \dot{r}_i^T \delta \dot{r}_i \right) \delta \ddot{r}_i dt + \sum_{i=1}^N \delta \left( \mu \dot{r}_i^T \delta \dot{r}_i \right) \delta \ddot{r}_i dt + \\
&\sum_{i=1}^N \delta M_i \delta \ddot{r}_i dt = 0 ,
\end{align*}$$

where $M_i$ is the driving torque acting on the $i$-th pulley, $r_i=r_i(s,\xi,t),
\left| r_i \right| = \sqrt{r_i^T r_i} = \sqrt{\frac{\partial r_i^T (L_i, \xi, t)}{\partial s} \frac{\partial r_i (L_i, \xi, t)}{\partial s}},
\left| r_i \right| = \sqrt{\frac{\partial \dot{r}_i^T (\dot{\xi}, t)}{\partial s} \frac{\partial \dot{r}_i (\dot{\xi}, t)}{\partial s}},
\left| r_i \right| = \sqrt{\frac{\partial r_i^T (\xi, t)}{\partial s} \frac{\partial r_i (\xi, t)}{\partial s}}.

The terms staying at the independent variations $\delta \ddot{r}_i$, $\delta \dot{r}_i$ and $\delta \ddot{r}_i$ have to be equal to zero and then it can be accessed to $N$ scalar equations

$$- \left( \mu \ddot{r}_i + \kappa \right) \dot{r}_i - \mu g d \sin \frac{\xi_i}{d} - EA H \left( r_i \right) \dot{r}_i^T \dot{r}_i - \frac{1}{2} M_i = 0 ,$$

to $N$ vector equations ($3N$ scalar equations)
\[ \ddot{r}_i = \frac{EA}{\mu} H \left( \left| \dot{r}_i \right| - 1 \right) \left[ \dot{r}_i \left| \dot{r}_i \right|^2 \right] + g \, e_3 \]  

(19)

and to 1 vector equation (3 scalar equations)

\[ \ddot{r}_L = \frac{EA}{m} H \left( \left| \dot{r}_L \right| - 1 \right) \left[ \dot{r}_L \left| \dot{r}_L \right|^2 \right] + g \, e_3, \]

(20)

where function \( H(\ ) \) represents Heaviside’s step function respecting only positive stretching (pull deformations) of individual cables. The first (scalar) equation corresponds to the moment equilibrium condition of each pulley, the second (vector) equation describes the equilibrium of the infinitesimal element of the \( i \)-th cable. The third (vector) equation corresponds to the equilibrium of the point mass (end-effector). The last equations have to be supplemented by boundary conditions, which in this case take the form of \( N \)-1 vector equation

\[ \ddot{r}_l = \ddot{r}_l(s_1, \xi, t) = \ddot{r}_l(s_2, \xi, t) = ... = \ddot{r}_l(s_N, \xi, t). \]  

(21)

Let’s approximate the solution in form

\[ r(s, \xi, t) = r_\xi + \Psi(s, \xi) a(t), \quad ( ) = \frac{\partial}{\partial s}, \quad r_\xi = r_\xi(s, \xi, t) = r_\xi + \Psi(L, \xi) a(t), \]

where \( a(t) \in \mathbb{R}^{3M} \) are unknown searched time functions,

\[ \Psi(s, \xi) = \begin{bmatrix} u(s, \xi) \\ u(s, \xi) \\ u(s, \xi) \end{bmatrix} \in \mathbb{R}^{3M}, M = 6, \]

\[ u(s, \xi) = \begin{bmatrix} s-\xi(t) \\ \frac{\xi(t)}{L} \\ \left( \frac{\xi(t)}{L} \right)^2 \\ ... \\ \left( \frac{\xi(t)}{L} \right)^6 \end{bmatrix} \in \mathbb{R}^6. \]
When it is assumed that $\xi(t)$ are prescribed time functions Eq. (18) serves only for the determination of pulley torques. Remaining Eqs. (19) and (20) after substituting approximation take form of $N$ vector equations

$$
\begin{align*}
\Psi_i^{(\xi)} & \vdash \dot{\xi}^2 a_i - \Psi_i^{(\xi)} \dot{\xi} \ddot{a}_i - 2\Psi_i^{(\xi)} \ddot{\xi} a_i + \Psi_i^{(\xi)} \dddot{a}_i = \\
& = \frac{E A}{\mu} \left\{ \frac{\Psi_i^{(\xi)}}{a_i} \dddot{a}_i - \frac{\Psi_i^{(\xi)}}{a_i^{1/2}} \Psi_i^{(\xi)} a_i \right\} + g e_i
\end{align*}
$$

and 1 vector equation ($k$ is the subscript corresponding to the end point of one chosen $k$-th cable)

$$
\begin{align*}
\Psi_{kL}^{(\xi)} & \vdash \dot{\xi}^2 a_k - \Psi_{kL}^{(\xi)} \dot{\xi} \ddot{a}_k - 2\Psi_{kL}^{(\xi)} \ddot{\xi} a_k + \Psi_{kL}^{(\xi)} \dddot{a}_k = g e_3 - \frac{E A}{\mu} \sum_{m=1}^{N} \frac{a_i^{1/2} \Psi_i^{(\xi)}}{\sqrt{a_i^{1/2} \Psi_i^{(\xi)} a_i}} - 1
\end{align*}
$$

Left hand side of Eq. (24) corresponds to the acceleration of mass point, which can be expressed as acceleration of end point of one chosen $k$-th cable. After approximation boundary conditions (21) have form

$$
\begin{align*}
\Psi_{(i+1)L}^{(\xi)} a_{i+1} - \Psi_{(i+1)L}^{(\xi)} \dot{\xi}_{i+1} - 2\Psi_{(i+1)L}^{(\xi)} \ddot{\xi}_{i+1} a_{i+1} + \Psi_{(i+1)L}^{(\xi)} \dddot{a}_{i+1} - \\
- \Psi_{(i+1)L}^{(\xi)} a_i - \Psi_{(i+1)L}^{(\xi)} \dot{\xi}_i - 2\Psi_{(i+1)L}^{(\xi)} \ddot{\xi}_i a_i + \Psi_{(i+1)L}^{(\xi)} \dddot{a}_i = 0, \quad i=1,2,\ldots,N-1.
\end{align*}
$$

Using Galerkin’s method for solving Eqs. (23), (24) and (25) each of Eqs. (23) is premultiplied by matrix $\Psi_i^{T}$ and integrated from $\xi_i$ to $L_i$,

where $\Psi_i(s, \xi_i) = \begin{bmatrix}
\tilde{u}(s, \xi_i) \\
\tilde{\tilde{u}}(s, \xi_i) \\
\tilde{\tilde{\tilde{u}}}(s, \xi_i)
\end{bmatrix} \in \mathbb{R}^{3(M-1)}$, $M=6$,

and $\tilde{u}(s, \xi_i) = \begin{bmatrix}
\frac{s-\xi_i(t)}{L_i}, \frac{(s-\xi_i(t))^2}{2L_i}, \frac{(s-\xi_i(t))^3}{3L_i}
\end{bmatrix} \in \mathbb{R}^{3}.$

Now it can be accessed to the total equation of motion in the form of

$$
M(t) \dddot{a}(t) + B(t) \dot{a}(t) + K(t) a(t) = f[a(t)],
$$

where $M(t), B(t), K(t) \in \mathbb{R}^{3MN,3MN}$, $f[a(t)] \in \mathbb{R}^{3MN}$, which is the system of nonlinear ordinary differential equations, whose solution can be obtained using e.g. the Runge-Kutta method.

**CONCLUSIONS**

This paper summarizes the possible approaches suitable for the modelling of cable and fibre dynamics in the framework of various mechanical systems. Force representation of the cable, a point-mass model, absolute nodal coordinate formulation (ANCF) and a general model involving cables with distributed mass and time-varying length based on Hamilton’s principle are introduced.
Future work will be focused on the implementation of the point-mass model of the cable and
the modelling of its interaction with the pulley (the advantage of this approach is supposed to
be in a precise physical interpretation of the problem and in a short computational time).
